Load transformation from the rotating into the fixed coordination system: Unbalance

stationary axial force in blade rotating (blade) system: unbalance results in $\Delta F = \Delta m \text{ rs } \Omega 2$

rotating excitation, so called fixed (nacelle) system: unbalance results in 1P-excitation

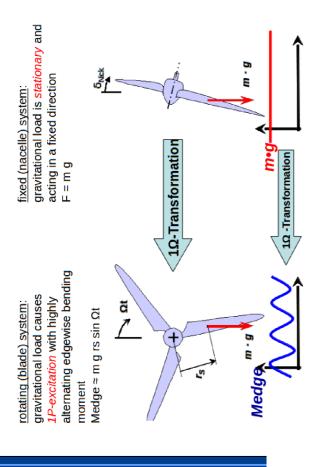

Fhorz = $\Delta m \text{ rs } \Omega 2 \sin \Omega t$

Variations of the dynamic design of the rotor nacelle system of a variable rotor speed turbine (1) (2) (3) (4)

Design ranges:

- Very soft, hardly possible due to strength requirements and excessive dynamic wave excitation (unless a compliant design with an eigenfrequency below the wave excitation is chosen)
 - window for stationary operation of the rotor speed, soft-soft design with quite significant wave Soft-soft design range in the resonance range of the rotor speed, requires an exclusion 3
 - excitation
- Classical soft-stiff design range, already resulting in significant wave excitation Blade resonance range with excessive excitation from cyclic aerodynamic loading, design $\odot 4$
 - impossible without a large exclusion window of the rotor speed Stiff-stiff, uneconomical design due to too high stiffness requirements

CARL OSSIETZKY Universität OLDENBURG

Tower design

- Mass
- Important in terms of economy
- Transport
- Dissipation of loads
- Buckling forces Extreme Loads
- Fatigue loads
- Natural frequency

[University of Western Australia]

Example for buckling

Transport:

Tower design

Producibility

[Bilfinger Berger]

Aeroelastic Simulation of Wind Turbines 05 Steady calculations / page 14

CARL OSSIETZKY Universität OLDENBURG

Remark

- Tower design very simplified
- Cylindrical tower
- Normally: Conical with more stations (hybrid)
- No preliminary load calculation done
 Buckling
- Extreme loads
- Fatigue loads
- No material selection
- No producibility check
- No transportability check

CARL OSSIETZKY Universität OLDENBURG

Tower design

- Eigenfrequency
- Influenced by modal mass and stiffness

$$oldsymbol{\omega}_0 = \sqrt{rac{k}{m_{
m modal}}} = f_0 \cdot 2\pi$$

Modal mass is approximated by swinging part of the tower + tower head mass

$$m_{\rm modal} = m_{\rm lowertop} + 0.25 \cdot m_{\rm lowermass}$$

Stiffness and mass are depending on the wall thickness

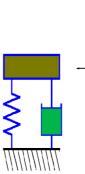

$$k = \frac{3EI}{I^3} \qquad I = \frac{\pi D^3 t}{8} \qquad \text{where} \\ \text{where} \qquad \text{where} \qquad \text{p = Material density} \\ k = \text{Suffness} \qquad I = \text{Moment of inertia} \qquad D = \text{Tower diameter} \\ E = E - \text{modulus} \qquad D = \text{Tower diameter} \qquad t = \text{Wall thickness} \\ I = \text{Moment of inertia} \qquad t = \text{Wall thickness} \qquad I = \text{Tower height} \\ \end{cases}$$

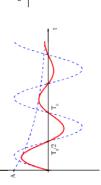

Eigenfrequency = Maximum rotor speed + 10%
